Fast radio bursts with CHIME

Kendrick Smith (Perimeter Institute) Berkeley, April 2024

Lead institutions:

THE UNIVERSITY OF BRITISH COLUMBIA

+ Smaller teams at these institutions:

Carnegie Mellon University

CHIME collaboration

- 1. The CHIME concept: moving difficulty from hardware to software
- Searching for fast radio bursts with CHIME 2.
- 3. Periodic phenomena in FRBs
- An FRB in the Milky Way 4.
- 5. A large FRB catalog
- 6. Coming soon: CHIME outriggers, CHORD

Traditional radio telescope

CHIME

Single-feed radio telescope

Focuses via physical delays: constructive interference only occurs for a specific direction on the sky

Phased-array interferometer

Dish is replaced by an array of antennas whose signals are digitized.

By summing signals with appropriate delays, can simulate the dish in software, and focus on part of the sky.

Can "repoint" telescope by changing delays.

Beamforming interferometer

Copy the digitized signals and repeat the computation N times (in parallel). Equivalent to N telescopes pointed in different directions.

CHIME

CHIME has a 4 x 256 array of antennas and can form all 1024 independent beams in real time. Raw sensitivity is the same as 1024 single-feed radio telescopes!

80m

Mapping speed

For many purposes, the statistical power of a radio telescope is proportional to its mapping speed:

 $M \approx (\text{Collecting area } A) \times (\text{Number of beams}) \times (\text{Order-one factors})$

	A	N_{beams}	$M/(10^5 \text{ m}^2)$
Parkes 64m	3200 m ²	13	0.41
Green Bank 100m	7850 m ²	7	0.55
Arecibo 300m (RIP)	70000 m ²	7	4.9
FAST 500m	200000 m ²	19	38
CHIME	6400 m ²	1024	66

The challenge

Parkes 64m Green Bank 100m Arecibo 300m (RIP) FAST 500m CHIME

In principle, sensitivity is proportional to mapping speed M, but computational cost is proportional to N_{beams} (or worse).

The CHIME design is really a strategy for moving difficulty from hardware to software.

A	$N_{\rm beams}$	$M/(10^5 \text{ m}^2)$
00 m ²	13	0.41
50 m ²	7	0.55
00 m ²	7	4.9
000 m ²	19	38
00 m ²	1024	66

CHIME computing

- 10 beams (repointable)
- Receives electric field at max resolution

Cosmology backend

Receives full visibility • matrix (2048²) at low time resolution (10 sec).

FRB search backend

- 1024 beams (fixed) •
- Gets intensity in 16384 • frequency channels, at 1 ms time resolution.

CHIME computing

LSST: 15 TB/day

- 10 beams (repointable)
- Receives electric field at max resolution

Cosmology backend

Receives full visibility • matrix (2048²) at low time resolution (10 sec).

FRB search backend

- 1024 beams (fixed) ullet
- Gets intensity in 16384 • frequency channels, at 1 ms time resolution.

- 1. The CHIME concept: moving difficulty from hardware to software
- 2. Searching for fast radio bursts with CHIME
- 3. Periodic phenomena in FRBs
- An FRB in the Milky Way 4.
- 5. A large FRB catalog
- 6. Coming soon: CHIME outriggers, CHORD

FRB mini-introduction (slide 1/4)

FRBs: a recent astrophysical phenomenon, discovered in 2007.

- Recall that when a radio pulse propagates through free electrons, it is dispersed: (Pulse arrival time) \propto (frequency)⁻²
- The prefactor (or "dispersion measure" DM) is the electron column density

$$\mathrm{DM} = \int dx \, n_e(x)$$

• Defining property of an FRB: observed DM exceeds the total column density of the Milky Way, suggesting an extragalactic origin.

FRB mini-introduction (slide 2/4)

Host galaxies: around ~20 FRBs have been observed with good enough angular resolution to uniquely determine a host galaxy (proving that FRBs are extragalactic).

Dissecting the DM:

 $DM = DM_{gal} + DM_{cosmo} + DM_{host}$

 $DM_{gal} = Milky Way contribution (can)$ be modelled and subtracted)

 $DM_{cosmo} = n_{e0} \int dz \, (1+z)/H(z)$ (largest contribution)

 $DM_{host} = FRB-local contribution$ (acts as "noise" on DM_{cosmo})

FRB mini-introduction (slide 3/4)

- Implication of comological distances: FRBs are ultra-energetic (~10⁵-10¹¹ times brighter than known sources in our Galaxy), suggesting a new emission mechanism.
- Explaining FRBs has become a central unsolved problem in astrophysics.
- When CHIME started operating in 2018, only ~30 FRBs were known. (Number is now ~700, around 500 of which have been found by CHIME.)

Blue = FRBs

Orange = well-understood Milky Way pulses

Bochenek et al (STARE2)

FRB mini-introduction (slide 4/4)

- Repeating FRBs: prior to CHIME, one FRB had been observed to repeat.
- In the first ~year of operation, CHIME found 18 new repeating FRB's, establishing that repetition is not uncommon.
- Open question: do all FRB's repeat, or are repeating and non-repeating FRB's different types of objects?

Do all FRBs repeat?

"bonsai": CHIME fast radio burst search software

From 2016-2018, we developed algorithms to search a CHIME-sized dataset for fast radio bursts (FRBs).

The CHIME FRB search software is:

- Orders of magnitude faster than other search software.
- Near statistically optimal
- Real-time, ~ 10 second latency
- Includes real-time RFI removal with very low • false positive rate

Maya Burhanpurkar

- 1. The CHIME concept: moving difficulty from hardware to software
- Searching for fast radio bursts with CHIME 2.
- 3. Periodic phenomena in FRBs
- An FRB in the Milky Way 4.
- A large FRB catalog 5.
- 6. Coming soon: CHIME outriggers, CHORD

CHIME FRB "greatest hits"

First phenomenon: periodic sub-pulses in an FRB

- A few FRBs show pulse train "microstructure".
- In this example (FRB20191221A), a ~3 second burst of activity can be resolved as a sum of ~ 9 overlapping pulses.

(After subtracting a well-motivated model for the pulses, residuals are consistent with noise.)

CHIME/FRB collaboration, arxiv:2107.08463

First phenomenon: periodic sub-pulses in an FRB

- We noticed that the arrival times are periodic (with 3 gaps), with best-fit period 217 ms.
- Formal significance is ~6.5 σ (p-value 7 × 10⁻¹¹), accounting for look-elsewhere effect in period and choice of gaps.
- 217 ms period suggests a neutron star origin.

CHIME/FRB collaboration, arxiv:2107.08463

- This repeating FRB ("R3") is the most active • repeating FRB in CHIME.
- Redshift z=0.0337 (EVN + Gemini).
- At the time, this was the closest known FRB. •

Nature 577 (2020) 190, arXiv:2001.02222

- or precession period.

A surprise: R3 is only active in 4-day windows, regularly spaced with period 16.35 days. Statistical significance was $\sim 4\sigma$ after 14 months of data, and has held up since then. Naturally explained in a neutron star model, as either orbital period (in a binary system)

Nature 582 (2020) 351, arXiv:2001.10275

- Statistical significance was $\sim 4\sigma$ after 14 months of data, and has held up since then.
- A surprise: R3 is only active in 4-day windows, regularly spaced with period 16.35 days. • Naturally explained in a neutron star model, as either orbital period (in a binary system)
- or precession period.
- We also observe a secular increase in rotation measure (RM), starting in 2021 (!)

Before showing the plot, I'll pause to define RM. Faraday rotation: a linearly polarized FRB propagating through a magnetic field has frequency-dependent rotation

(rotation angle) = (RM) λ^2 where

$$\mathrm{RM} \propto \int dx \, n_e(x) B_{\parallel}(x)$$

The "rotation measure" RM probes the magnetic environment along the line-of-sight.

- or precession period.
- We also observe a secular increase in rotation measure (RM), starting in 2021 (!)

A surprise: R3 is only active in 4-day windows, regularly spaced with period 16.35 days. Statistical significance was $\sim 4\sigma$ after 14 months of data, and has held up since then. Naturally explained in a neutron star model, as either orbital period (in a binary system)

Mckinven et al, ApJ 950 (2003) 12

- 1. The CHIME concept: moving difficulty from hardware to software
- Searching for fast radio bursts with CHIME 2.
- 3. Periodic phenomena in FRBs
- 4. An FRB in the Milky Way
- 5. A large FRB catalog
- 6. Coming soon: CHIME outriggers, CHORD

• FRBs are much brighter ($\sim 10^{36}$ to 10^{42} ergs) than the brightest pulses ever are a puzzle in the first place!

observed from neutron stars in the Milky Way (~10³¹ ergs). This is why FRBs

Nature 587 (2020) 54-58

- FRBs are much brighter ($\sim 10^{36}$ to 10^{42} ergs) than the brightest pulses ever are a puzzle in the first place!
- In April 2020, CHIME observed two pulses from a known magnetar (SGR) 1935+2154) with energy (3 x 10³⁴) ergs! (The first pulse was also seen by ARO; the second pulse was also seen by STARE2 at 1.4 GHz.)

observed from neutron stars in the Milky Way (~10³¹ ergs). This is why FRBs

Nature 587 (2020) 54-58

- If this pulse had come from a nearby galaxy, it would be bright enough to qualify as an FRB.
- Implication: at least some FRBs are magnetars!
- It's natural to speculate that all FRBs are magnetars. However, the plot thickens....

Blue = FRBs

Orange = well-understood Milky Way pulses

Bochenek et al (STARE2)

An FRB in an old globular cluster

- FRB 20200120E: repeating FRB discovered in CHIME (3 bursts observed).
- Localized by EVN to old (~ 10^{10} years) globular cluster near the M81 galaxy (redshift $z \sim 10^{-3}$)
- But, an old globular cluster should have negligible recent star formation. How can there be magnetars?
- Merger-induced collapse may be a viable mechanism (e.g. Kremer et al arXiv:2210.04907).

Kirsten et al 2105.11445

- Several X-ray telescopes observed X-ray pulses coincident with the radio pulses.
- magnetar FRB models predict $L \ge 0$ (i.e. radio arrives later).

• Arrival time lag $L = t_{radio} - t_{x-ray}$ is very constraining for models. As far as I know, all

- Several X-ray telescopes observed X-ray pulses coincident with the radio pulses.
- Arrival time lag $L = t_{radio} t_{x-ray}$ is very constraining for models. As far as I know, all magnetar FRB models predict $L \ge 0$ (i.e. radio arrives later).
- The first reported X-ray measurements (INTEGRAL) found $L = (-6.5 \pm 1)$ ms!

INTEGRAL collaboration (Mereghetti et al), 2005.06335

- Shortly thereafter, two more X-ray experiments published timings.
- Insight-HXMT is consistent with INTEGRAL (chi²=4.2, dof=2, p=0.12), and increases significance of L < 0 to 8.5 sigma.

- Shortly thereafter, two more X-ray experiments published timings.
- Insight-HXMT is consistent with INTEGRAL ($chi^2=4.2$, dof=2, p=0.12), and increases significance of L < 0 to 8.5 sigma.
- Konus-Wind shows no preference for L < 0, but doesn't report error bars.

(For what it's worth, the Konus-Wind instrumental resolution is 2 ms, versus 0.061 ms for INTEGRAL and 1 ms for Insight-HXMT.)

- 1. The CHIME concept: moving difficulty from hardware to software
- Searching for fast radio bursts with CHIME 2.
- 3. Periodic phenomena in FRBs
- 4. An FRB in the Milky Way
- 5. A large FRB catalog
- 6. Coming soon: CHIME outriggers, CHORD

492 total sources, 18 of which are repeaters! Larger catalogs coming soon (CHIME has found a few thousand FRBs so far.)

CHIME/FRB collaboration, arxiv:2106.04352, ApJ accepted

Main technical challenge: modelling selection function of telescope. We use a Monte Carlo approach: inject simulated pulses in real search.

Constraints on overall FRB population:

• FRB luminosity function is consistent with a power law: $N(\geq S) \propto S^{\alpha}$

> Exponent $\alpha = -1.40 \pm 0.11(\text{stat.})^{+0.06}_{-0.00}(\text{sys.})$ Consistent with Euclidean $\alpha = -3/2$.

• Total rate $[525 \pm 30(\text{stat.})^{+140}_{-130}(\text{sys.})]/\text{sky/day}$

with cuts: fluence ≥ 5 Jy-ms $DM \ge 100 \text{ pc cm}^{-3}$ scattering time $\tau_{600} \leq 10$ ms.

CHIME/FRB collaboration, arxiv:2106.04352, ApJ accepted

Constraints on FRB model parameters.

Two examples shown here: intrinsic width w, and scattering time τ .

Technical note: FRB pulse profiles are modelled as convolution of two contributions:

- Gaussian "intrinsic" profile with width w
- Exponential "scattering" profile with width τ

Scattering time τ is an example where the selection function qualitatively changes the interpretation.

> **CHIME/FRB** collaboration, arxiv:2106.04352, ApJ accepted

- $(p \sim \text{few} \times 10^{-8})$ than non-repeaters.
- Tentative evidence that repeaters have higher DM ($p \sim 0.01$).

CHIME / FRB collaboration, ApJS 257 (2021) 59, arXiv:2106.04352 CHIME/FRB collaboration, ApJ accepted, arXiv:2301.08762

• Repeaters have longer-duration pulses ($p \sim \text{few} \times 10^{-5}$) and narrower bandwidths

• Other source properties (brightness, polarization) are consistent between populations.

Using FRB-galaxy correlations to learn about FRBs

- CHIME angular resolution is insufficient to associate individual FRBs with individual galaxies.
- By spatially correlating FRBs and galaxies, we see a high significance (5 σ) statistical association.
- First evidence for high-DM FRBs (DM ~ 800) at intermediate redshifts ($z \sim 0.4$), later confirmed by other telescopes.
- Much higher statistical significance coming soon!

Masoud Rafiei-Ravandi

Rafiei-Ravandi et al, ApJ

- foreground galaxies with "DM maps" from background FRBs.
- Can break the optical depth degeneracy in kSZ.
- parameters for cosmic shear analyses.

k (1/Mpc)

• Future application: galaxy-electron power spectrum $P_{ge}(k)$, by spatially correlating

• Complementary to kSZ (noise power spectra have different k dependence).

• Measuring $P_{ge}(k)$ is astrophysically interesting and can pin down nuisance

- 6. Coming soon: CHIME outriggers, CHORD

- When CHIME core detects an FRB, it tells the outriggers to save voltage data to disk.
- Outriggers do nothing except ring-buffer data, and save to disk on command.
- Later, data can be shipped to computing cluster for VLBI analysis.

Proof of concept: an FRB localized to a disk galaxy at z=0.18

Localization accuracy ~1 arcsec, using ad hoc VLBI network (CHIME + ARO + TONE). Limited by calibration systematics — hope to get 50 milliarcsec with CHIME outriggers!

Cassanelli et al, arXiv:2307.09502

Coming soon: CHORD (Canadian successor to CHIME)

New technology under development:

- Wide-band feeds (300-1500 MHz).
- Lower noise, aiming for $T_{sys} \sim 30 \text{ K}$ (CHIME is ~50 K).
- Using 512 6-m dishes, total collecting area (120 m)².
- Effective mapping speed ~10 times higher than CHIME.
- Outriggers for VLBI resolution.
- "Pathfinder" expected 2024/5, full instrument expected 2026.

• For \$15M USD, you can build one of the world's most powerful radio telescopes (!)

- speed) in the near future. (CHORD represents the first factor of ~ 10 .)

- I'm convinced that the future of radio astronomy is "large N and clever algorithms".
- CHIME/CHORD are ambitious steps in this direction. We have solved some difficult computational problems (CHIME-scale FRB search!), but more challenges remain.

Radio astronomy may be "scaled up" by orders of magnitude in the near future. The discovery space is huge!

- what are they?
- potential applications...?

21-cm cosmology:

- •

3D "super CMB"

• most powerful way (?) to measure many cosmological parameters (early universe, neutrinos, dark matter, etc.)

Pulsars:

- new tests of GR
- new probe of gravity waves
- rich astrophysics

Thanks.

Two parameters control the pulse width, "scattering time" τ_{600} and "intrinsic width" w

"Intrinsic" profile: Gaussian, width w frequencyindependent

"Scattering" Profile:

Exponential, timescale = $(f/600 \text{ MHz})^{-4}$

CHIME beamforming, cartoon form

Each antenna sees a narrow strip on the sky ("primary beam"). By beamforming in software as previously described, we can make 1024 "formed" beams with size ~ 0.3 degree.

primary beam

formed beams

CHIME beamforming, cartoon form

As the Earth rotates, the primary and formed beams sweep over the sky.

Every 24 hours, we make an image of the range 400-800 MHz.

Every 24 hours, we make an image of the sky with 0.3 degree resolution, in frequency
